Intrinsic organization of the thalamic reticular nucleus: relation to thalamocortical relations. The thalamic reticular nucleus (RE) is an important relay between the ventrobasal (VB) thalamus and other thalamic structures, as well as between the cerebral cortex and VB. For the latter, it forms an important route of topographic projection. Its capacity to process inputs from both areas, however, is dependent on intratremal interactions. Little is known about the organization of the RE with respect to these relations, particularly whether specific subnuclei have a unique domain of influence. In the present study, the architecture of the RE was examined within a series of horizontal sections taken from both hemispheres of a single Golgi-impregnated, normal adult cat. The findings were compared with the patterns of thalamocortical topography derived from the same material in the same animal. This comparison indicated that thalamocortical fibers frequently traverse the RE, but that they frequently also converge in the RE. This can be interpreted as reflecting an organizational principle of the RE that is related to its functions in transmodal processing.
